

# Amortized performance and `std::vector`'s memory management

*COMP.CS.300 Data structures and algorithms 1*

*Matti Rintala (matti.rintala@tuni.fi)*

# STL vector memory management

- Vector reserves a continuous memory block for its elements
- What to do when it needs more space?

1

- Attempt 1: reserve new memory block with as much more space as you need, copy old elements there

# STL vector memory management

- Vector reserves a continuous memory block for its elements
- What to do when it needs more space?
- Attempt 1: reserve new memory block with as much more space as you need, copy old elements there

# STL vector memory management

- Vector reserves a continuous memory block for its elements
- What to do when it needs more space?

1

- Attempt 2: reserve **twice as large** memory block, copy old elements there
- Note: Some memory remains unused!

- Attempt 2: reserve **twice as large** memory block, copy old elements there
- Note: Some memory remains unused!

# *Amortized* tehokkuus

- Counts average performance of *operation sequences*
- Cost of expensive rare operation can be spread evenly on cheap operations
- E.g., append an element to vector:
  - Individual insertion can be linear (gets rarer and rarer)
  - Insertions are still *amortized* constant time (on average)

# std::vector

- STL vector contains operations for tweaking memory management
- `vec.reserve(n)`: Reserves *memory* at least for *n* elements, elements are still not (yet) added
- `vec.capacity()`: Maximum number of elements without new memory allocation
- `vec.shrink_to_fit()`: Move elements to memory block that is just the right size
- (`vec.erase()` *does not* free memory!)
